

**Monitoring of the biodegradation of toluene-contaminated sand in columns
by SIP measurements, CO₂ content and its ¹³C/¹²C isotopic signature**

Hydrocarbon contaminated soils represent an environmental issue as it impacts on ecosystems and aquifers. Bioremediation uses the ability of bacteria naturally present in the ground to degrade hydrocarbons. It represents an effective solution to fight the pollution but *in situ* monitoring before and during soil treatment is difficult and challenging. Indeed, where significant subsurface heterogeneity exists, conventional intrusive groundwater sampling can be insufficient to obtain a robust monitoring as the information they provide is restricted to vertical profiles at discrete locations, with no information between sampling points.

In order to obtain wider information, complementary methods can be used like geo-electrical techniques. Induced polarization (IP) seems to be the more promising to study the effects of biodegradation processes. Indeed, laboratory and field experiments have shown an enhancement of real and imaginary parts of electrical conductivity while bacterial treatment is progressing (Abdel Aal et al. 2006; Atekwana et Atekwana 2010).

Moreover, microbial activity induced CO₂ production and isotopic deviation of carbon (Aggarwal and Hinchee 1991). The ratio $\delta^{13}\text{C}(\text{CO}_2)$ will come closer to $\delta^{13}\text{C}(\text{hydrocarbon})$.

From these findings, the French project *BIOPHY*, supported by the French National Research Agency (ANR), proposes to use electrical methods and gas analyses to develop a non-destructive method for monitoring *in situ* biodegradation of hydrocarbons in order to optimize soil treatment. Laboratory experiments in columns are carried out to demonstrate its feasibility.

Our objectives were to monitor aerobic microbial activity in toluene-contaminated sand columns using complex electrical resistivity measurements (SIP, Spectral Induced polarization and GEIS, Galvanostatic Electrochemical Impedance Spectroscopy) and measuring concentration and $\delta^{13}\text{C}$ isotopic ratio of produced CO₂.

Materials and methods

Toluene aerobic biodegradation by *Rhodococcus wratislaviensis* (*R. w.*) is studied. Columns (height 50 cm, diameter 15 cm) are constructed in Kynar® and filled with sand from Fontainebleau. They are fed up with a fluid containing toluene (carbon source), bacterial growth medium and H₂O₂ in low concentration to supply O₂ and thus stimulate aerobic metabolic bioprocesses.

Complex electrical conductivity measurements are performed regularly to monitor the bioactivity and progress of toluene degradation. Two methods are used: SIP and GEIS. An electrical current with known amplitude and frequency is applied at two ring electrodes, positioned at both ends of the columns. This induces an electrical current in the porous media and the associated voltage is measured between two Cu/CuSO₄ potential electrodes. The change of amplitude and phase of the received waveform allows measuring complex conductivity σ^* , expressed as a sum of the real (σ') and imaginary (σ'') parts:

$$\sigma^*(\omega) = \sigma'(\omega) + i\sigma''(\omega) \quad \text{with} \quad i = \sqrt{-1} \quad \text{and} \quad \omega = 2\pi f.$$

The CO₂ concentration and $\delta^{13}\text{C}(\text{CO}_2)$ is measured by infrared laser spectroscopy. Chemical composition of fluid is also monitored: toluene quantification, $\delta^{13}\text{C}(\text{toluene})$ and $\delta^{13}\text{C}(\text{DIC})$ (Dissolved Inorganic Carbon) and alkalinity.

Results and discussion

We show the results for two columns in Fig. 1: a biotic and an abiotic control.

For the biotic column, we notice an enhancement of σ'' during decrease of toluene concentration. Moreover, there is an increase of CO₂ concentration in the air just after increase of HCO₃⁻ concentration in the pore fluid; and $\delta^{13}\text{C}(\text{CO}_2)$ approaches $\delta^{13}\text{C}(\text{toluene})$. On the contrary,

for the abiotic column, there is no significant variation of the different parameters. The $\delta^{13}\text{C}(\text{CO}_2)$ was not able to be measured because of the lack of CO_2 in the air of the column.

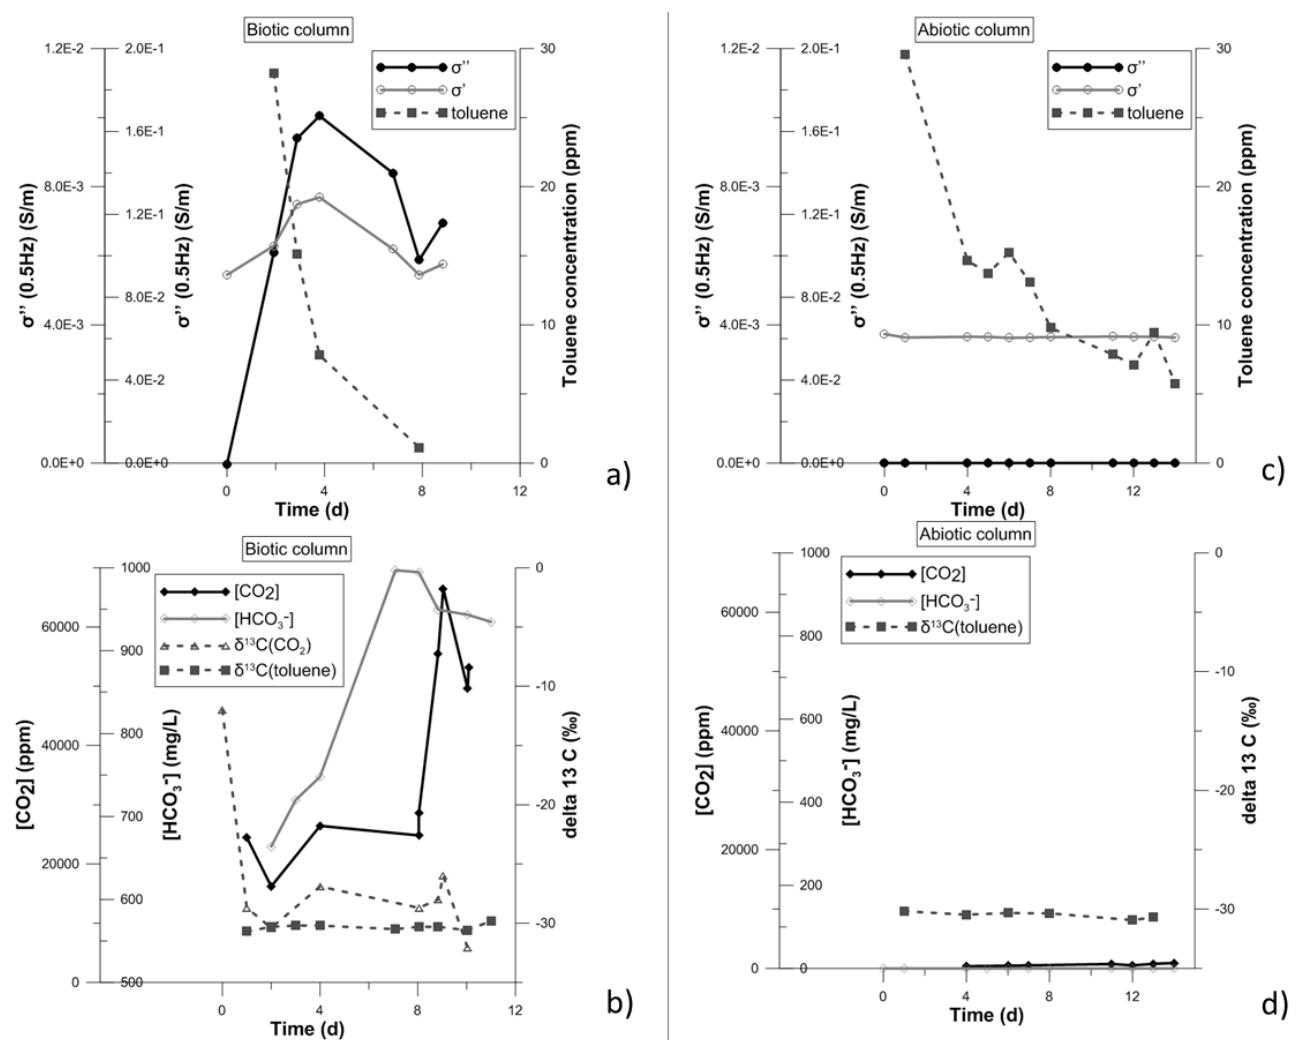

Fig. 1: Results for biotic (left) and abiotic (right) columns. a) and c) Variation over time of real and imaginary parts of complex conductivity at 0.5 Hz and toluene concentration; b) and d) CO_2 and HCO_3^- concentrations; $\delta^{13}\text{C}(\text{CO}_2)$ and $\delta^{13}\text{C}(\text{toluene})$.

Regarding these results, we can say that microbial activity is characterized by CO_2 production and $\delta^{13}\text{C}(\text{CO}_2)$ isotopic deviation, and also by an evolution of complex electrical resistivity in correlation with chemical analyses. Aerobic biodegradation of toluene can be monitored by SIP and gas measurements at laboratory scale and it will be tested soon on the field scale.
